## 1. Remote Backup

---

The Remote Backup offers the ability to store your backups automatically on a remote FTP server. Compared to a local backup remote backup has the advantage that the data is still available in case of system failure, because the Backups are stored externally.

This feature can be activated on your **WebAdmin** website of your IACBOX in menu **System/Backup**. Once the feature is activated, the following configuration dialog appears:

### Remote Backup

### 1.1 Configuration

---

Here the connection to the FTP server is configured.

- **Type:**  
Remote backup server type (currently only FTP is available).
- **Host:**  
IP address of the remote server.
- **Remote Directory:**  
Directory on the remote server where the backups are stored. The directory entered here must exist on the remote server actually!
- **Max. Generations:**  
Number of stored backup generations.
- **Username:**  
Remote server username.
- **Password:**  
Remote server password.

- **Manage remote files:**

If this feature is enabled, the backup files can be managed through the WebAdmin interface.

After saving the settings, the service can be started manually to test the settings. Now the backups are stored automatically every day at 03:00 on the remote server.

**Please verify that the backup file is available on the remote server!**
